16. Abstract This report presents the results of two full-scale, head-on collisions between the NHTSA Test Device and 1975 Plymouth Fury four-door sedans. The objective of these tests was to help establish a test methodology for evaluating crash compatibility and aggressiveness. The Test Device is a unique, honeycomb-faced, load-measuring tool which is adaptable to both moving barrier and fixed barrier collisions.		
Data contained in this report includes graphical and tabular presentations of vehicle deformation, Test Device load cell data, vehicle and simulated occupant acceleration, velocity and displacement values, dynamic displacement of string potentiometers, and restraint survival distances. Also included are tabular summaries of occupant injury criteria, exterior and interior static vehicle deformation, and restraint system loads and vehicle descriptions. Data for a 40-mph fixed Test Device collision is compared to that for an "equivalent" moving Test Device collision.		
17. Key Words Fixed Test Device, Moving Test Device, Compatibility, Aggressiveness, Plymouth Fury		18. Distribution Statement Document is available to the public through the National Technical Information Service, Springfield, Virginia 22161

1.0 INTRODUCTION

A series of eight full-scale crash tests was conducted to establish a test methodology for evaluating vehicle crash compatibilities and aggressiveness. The objectives of these tests were:

- To obtain the necessary data for establishing appropriate criteria for evaluating vehicle aggressiveness of intermediate, subcompact, and lightweight subcompact-size cars. The vehicles tested were all 1975 model cars which included Honda Civic CVCC, Volvo 244DL, Ford Torino, and Plymouth Fury.
- To investigate the Dynamic Science segmented load cell Test Device concept for sensitivity to measure the basic types of aggressiveness, namely, architectural, mass, and structural aggressiveness.

A summary of the car-to-Test Device test conditions is shown in Table 1-1. This test report presents the results of Tests No. 7 and 8, head-on collisions between the NHTSA Test Device and the 1975 Plymouth Fury four-door sedans.

The Test Device is a unique honeycomb-faced load-measuring tool which is adaptable to both moving barrier collisions (see Figure 1-1) and fixed-barrier collisions (see Figure 1-2). The barrier face of the Test Device is made up of 40 six-inch-thick energy-absorbing aluminum honeycomb modules, each individually connected to load cells. At selected locations, 6 string potentiometers were added to record honeycomb dynamic displacement. The Plymouth car was first crashed into the fixed Test Device (Test 7), and then a similar model was test d into the moving Test Device (Test 8). The closing speed for the moving Test Device tests was selected to give the same energy change (ΔE) as in the corresponding fixed Test Device test. (See Appendix A for determination of equivalent closing speed for moving Test Device collisions.)

TABLE 1-1. SUMMARY OF CAR-TO-TEST DEVICE TEST CONDITIONS

2.0 TEST METHODOLOGY AND PROCEDURE

This section presents a brief description of the test methodology and procedures used for conducting the Plymouth-to-Test Device head-on collisions.

2.1 VEHICLE DESCRIPTION

The vehicles used in these tests were both 1975 Plymouth Fury four-door sedans. Tables 2-1 and 2-2 present the incoming vehicle inspection performed on each car used for the fixed and moving Test Device tests, respectively.

For the tests to be conducted, two Part 572, male 50th percentile Alderson anthropomorphic dummies (GFE) were in the two front seating positions of the car. Each occupant was properly restrained with the vehicle's lap and shoulder belt restraint system. The seat tracks were welded in their midposition with the seat back latches secured to prevent breakaway and rotation. Test weights for the Plymouths were determined by averaging test weights of cars used in other crashes. Both collisions were head-on with no lateral offset distance between car and Test Device face.

2.2 FIXED TEST DEVICE TESTS

The Plymouth-to-fixed Test Device test was conducted at the barrier impact facility (see Figure 2-1) with the centerline of the test car in line with the centerline of the fixed Test Device face. The vehicle impact velocity (see Table 1-1) was controlled to within ± 1 mph.

1. Is the vehicle stock throughout? Describe No, 40 pounds of water added to fuel tank as ballast to meet weight goal.
2. Does vehicle show evidence of prior accident history? Describe No
3. Does vehicle show any significant corrosion? Describe No
4. Check condition of the front bumper and frame Includes two front bumper guards.

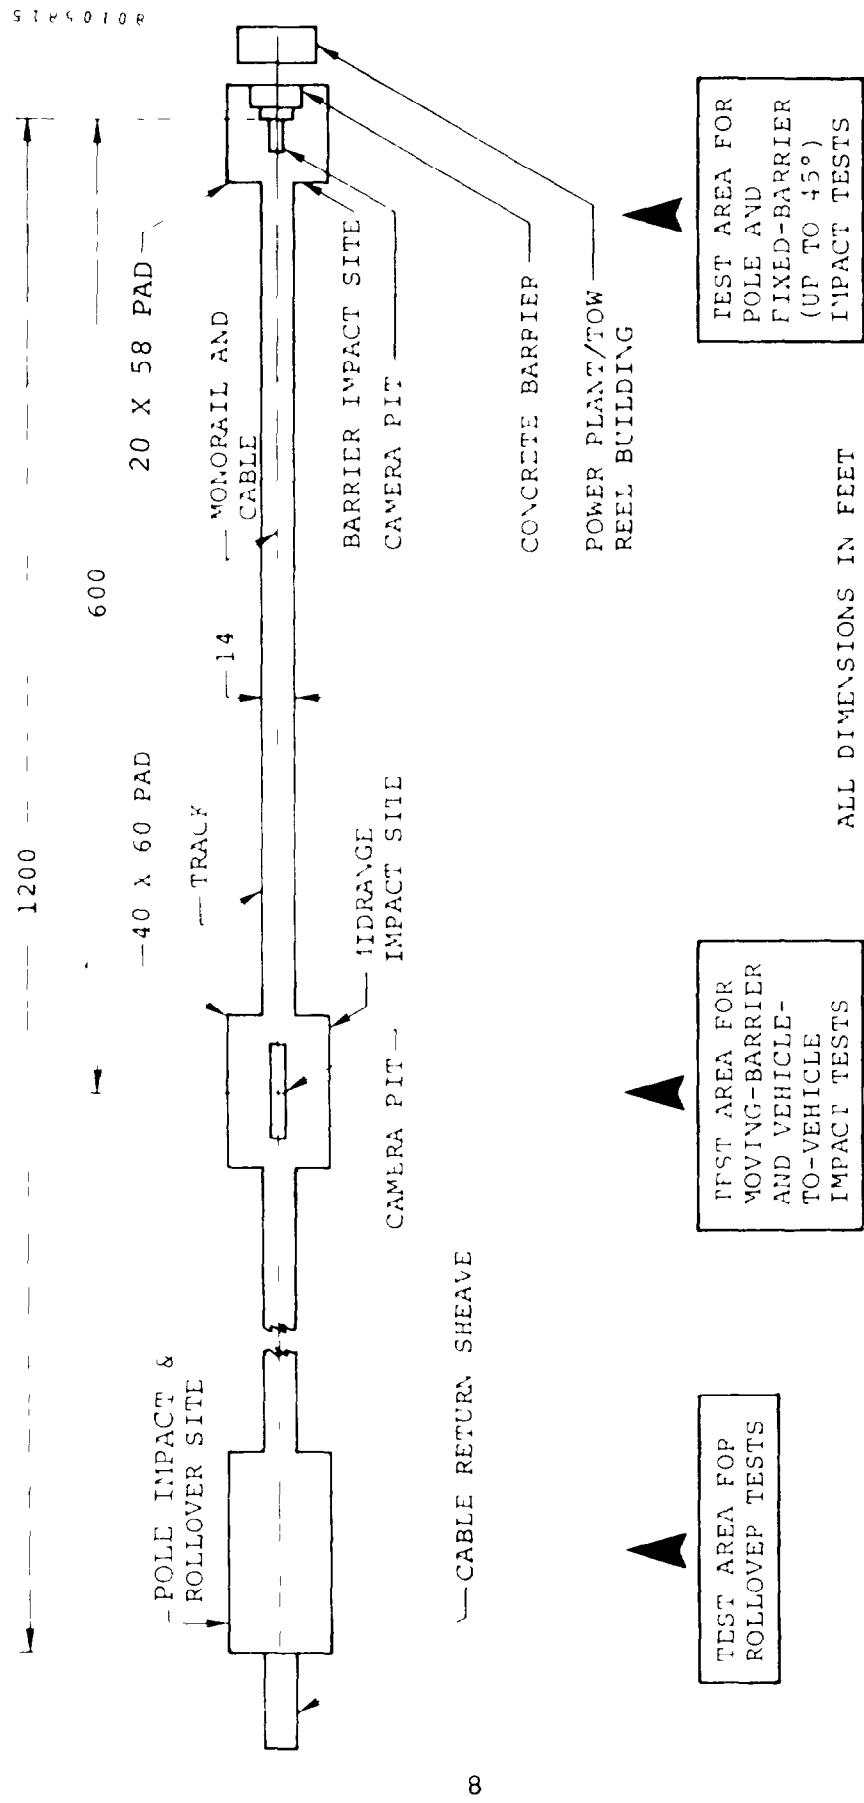

Figure 2-1. Monorail Impact Facility.

The test vehicle was instrumented with 16 accelerometers, 1 string potentiometer, 6 seat belt loads, and an impact sensor. The test vehicle was placed at the head of the test track facing the barrier where it was attached to the tow and guidance system. The fixed Test Device was instrumented with 4) load cells, 6 string potentiometers, 2 strain gauges, and an impact sensor.

Upon completion of the pre-crash checkout of the instrumentation, the vehicle was towed to the specified test speed and released from the tow system just prior to impact. The data from the test vehicle was transmitted to the data acquisition center via umbilical cable with telemetry as a backup. The data from the fixed Test Device were transmitted by umbilical cable only (see Figure 2-2). In order to achieve the weight goal outlined in the test plan, 30 pounds of water was added to the fuel tank of the test vehicle prior to testing. See Table 2-3 for a crash test summary of the fixed Test Device configuration.

2.3 MOVING TEST DEVICE TESTS

The Plymouth-to-moving Test Device test was conducted at the midrange station of the crash track facility (see Figure 2-1) with the centerline of the test car in line with the center of the moving Test Device face. The vehicle impact velocity of each test vehicle (see Table 1-1) was controlled to within ± 1 mph.

The test vehicle was instrumented exactly the same as the vehicle used in the fixed Test Device tests with the abort bottle placed inside the trunk of the vehicle. This was done for safety reasons. The test vehicle was placed at the head of the test

track, facing the barrier. The moving Test Device was instrumented the same as the fixed Test Device with the addition of 2 longitudinal accelerometers and an additional strain gauge attached to the frame rails of the moving Test Device. The moving Test Device was placed at the barrier end of the track. See Table 2-4 for a crash test summary of the moving Test Device configuration. To meet the test weight of the vehicle called out in the test plan, 40 pounds of water was used as ballast and added to the fuel tank.

Both vehicles were attached to the tow and guidance system. After the pre-crash checkout of the instrumentation, the vehicles were towed to the specified test speed and released from the tow system just prior to impact. The data from the test vehicle and moving Test Device were transmitted to the data acquisition center via umbilical cable with telemetry as a backup (see Figure 2-3).

3.2 INSTRUMENTATION

3.2.1 Test Vehicle Instrumentation

The test vehicle contained two Part 572 anthropomorphic dummies positioned in the left and right front seating locations. Prior to each test use, the dummies were inspected and adjusted to meet the torque and characteristic requirements for these devices. Sixteen structural accelerometers and one string potentiometer were installed on the vehicle and consisted of the following (see Figure 3-1):

1. A biaxial (X, Z) mount located on the left rocker panel near the B-pillar to measure accelerations of the occupant compartment.
2. A biaxial (X, Z) mount similar to No. 1, but on the right side of the vehicle.
3. A biaxial mount (X, Z) located on the rear floor structure over the rear axle.
4. A biaxial mount (X, Z) located on the upper centerline of the firewall in the engine compartment to measure acceleration of the forward section of the passenger compartment.
5. A biaxial mount (X, Z) located on the centerline of the rear axle to measure acceleration of the rear drive train and rear suspension assembly.
6. A single mount (X) located on the top of the engine block in a protective case to measure acceleration of the engine.
7. A single mount (X) located on the front frame cross-member in a protective case to measure axial acceleration of the front frame.
8. A triaxial mount (X, Y, Z) located near the vehicle center of gravity on the drive tunnel at the longitudinal C.G. to measure acceleration of the compartment.
9. A single mount (X) located in a position similar to that in No. 6, but on the bottom of the engine.

10. A string potentiometer installed on the interior firewall to measure the intrusion of the firewall into the occupant compartment.
11. A tape switch mounted onto the forwardmost portion of the car to record impact.

3.2.2 Test Vehicle Occupant Instrumentation

The following test dummy instrumentation was installed for the driver and right front passenger positions:

1. A triaxial accelerometer mount located in the head to measure its acceleration.
2. A triaxial accelerometer mount located in the chest cavity to measure chest acceleration.
3. A femur load cell mounted in the femur of each leg to measure femur loads.
4. Two seat belt load cells were mounted onto the lap belt with an additional seat belt load cell mounted onto the shoulder belt for each of the two front occupant restraint systems. The lap belt load cells were mounted on each side of the occupant.

The instrumentation requirements for the dummy occupants are given in Table 3-2.

3.2.3 Moving Test Device Instrumentation

The moving Test Device was instrumented with 40 load cells, 6 displacement string potentiometers, 3 strain gauges, 2 accelerometers, and 1 tape switch. Their purposes and locations were as follows:

1. A load cell mounted between each honeycomb module and Test Device rigid face to measure impact forces.
2. A string potentiometer displacement transducer mounted at selected honeycomb locations to measure dynamic honeycomb displacement.

Passenger left and right femur load cell					3000 lb		

*In G.

3. A single (X) accelerometer mounted on the longitudinal frame rails (mounted on each side) to measure acceleration of the Test Device.
4. Two strain gauges mounted on selected horizontal impact face beams to measure strains developed in the front structure due to the impact force.
5. One strain gauge mounted on the right side of the Test Device longitudinal frame rail to measure strain in the vehicle frame structure.
6. One tape switch mounted onto a selected honeycomb module to record the time of impact.

Figure 3-2 defines the typical instrumentation honeycomb module; Figure 3-3 describes the location of instrumentation on the Test Device impact face; and Figure 3-4 shows the location of the instrumentation on the Test Device vehicle structure.

3.2.4 Fixed Test Device Instrumentation

The instrumentation on the fixed Test Device was the same as on the moving Test Device except that the strain gauges and accelerometers on the Test Device frame were deleted (Figure 3-5).

3.3 PHOTO-INSTRUMENTATION RFQUIREMFNTS

3.3.1 Fixed Test Device Photography

Six high-speed (four 1000 fps and two 500 fps) cameras and one panning (24 fps) camera were used as shown in Table 3-3 for the fixed Test Device/moving vehicle tests.

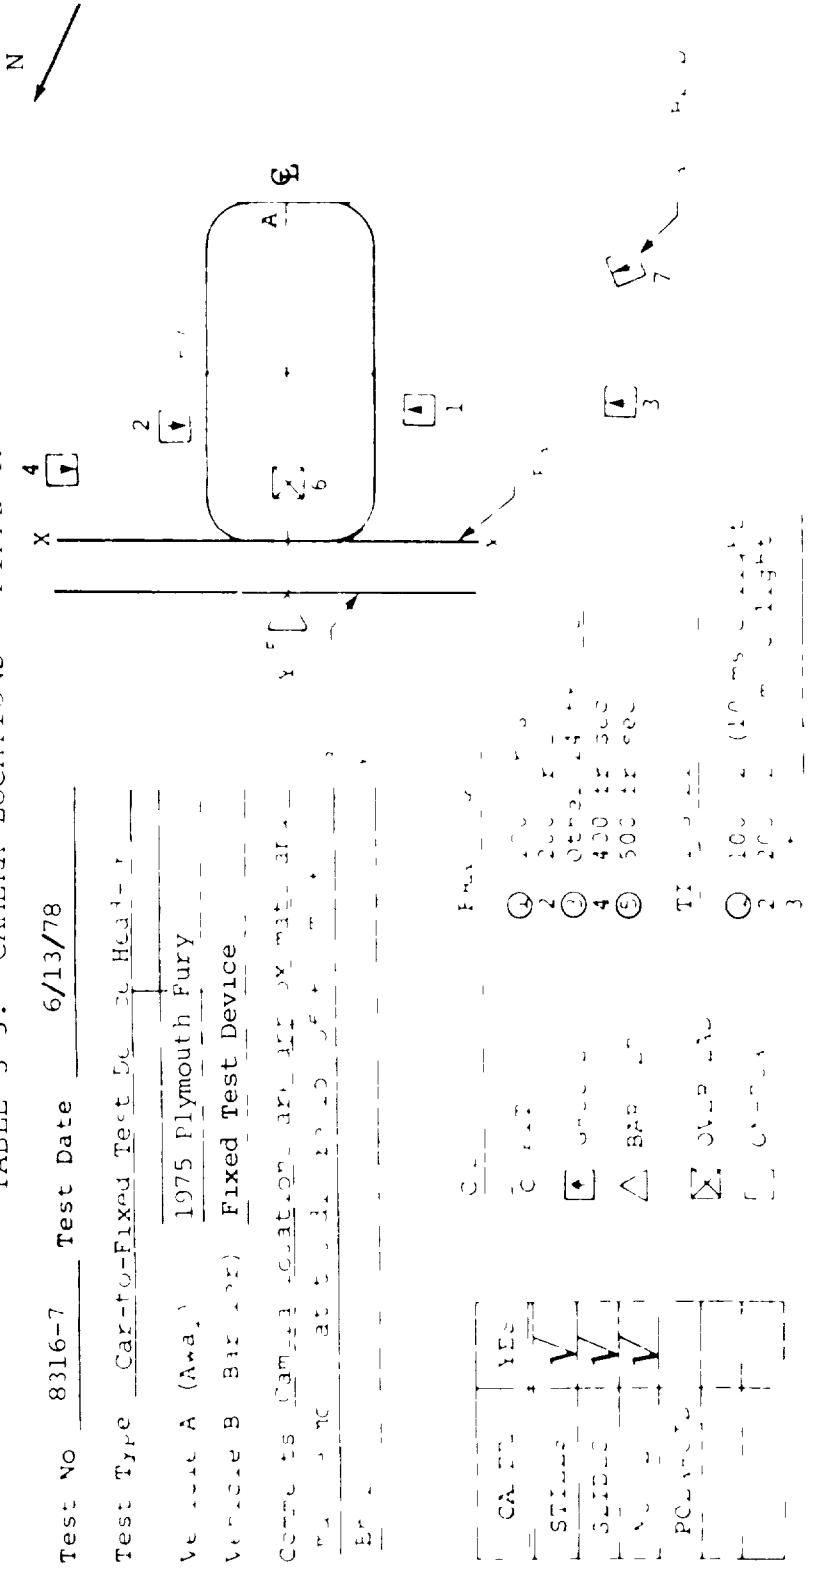

The panning camera documented the instrumentation, pre-test and post-test configurations, pre-test and post-test dummy positions, and the Test Device and vehicle crush profiles.

3.3.2 Moving Test Device Photography

Six high-speed (four 1000 fps and two 500 fps) cameras and one panning (24 fps) camera were used as shown in Table 3-4 for the moving Test Device/moving vehicle tests.

4.0 SUMMARY OF TEST RESULTS

This section of the report presents the results of the Plymouth-to-Test Device crash tests performed under Task 4. Copies of instrumentation data traces (Calcomp plots) are included in Appendix B for Test No. 7 and in Appendix C for Test No. 8.

4.1 TEST SUMMARY: PLYMOUTH-TO-TEST DEVICE TESTS

A summary of pertinent pre-test and post-test Test Device conditions are given in Tables 4-1 through 4-7. Pre-test and post-test views of crash configurations are shown in Figures 4-1 and 4-2 for fixed Test Device tests and in Figures 4-3 and 4-4 for moving Test Device tests.

Test weights for each vehicle were determined by weighing each wheel of the car to obtain a total weight. The vehicle was then rotated 180 degrees and the weighing procedure repeated to obtain an average weight for the vehicle.

Compartment and engine acceleration was determined by an averaging of accelerometers located near the B-pillar of the vehicle and the top and bottom of the engine block (see Figure 3-1).

Maximum mutual dynamic crush data, as well as the chronology of events for each vehicle, were determined by high-speed film analysis. Maximum dynamic crush on the car was determined by subtracting 6 inches of honeycomb crush from the maximum mutual dynamic crush for each test.

4.1.1 Fixed Test Device Test

In the fixed Test Device test, the Plymouth impacted the aluminum honeycomb modules at a speed of 40.7 mph, causing approximately 25.6 inches of static crush to the vehicle. The final speed of the Plymouth was -6.7 mph, giving a total velocity change of 47.4 mph.

Figure 4-2. Post-test Vehicle Configuration - Test 7.

Figure 4-3. Pre-test Vehicle Configuration - Test 8.

NOTE: TEST DEVICE PUSHED BACK BY CAR APPROXIMATELY 23 FEET.

Figure 4-4. Post-test Vehicle Configuration - Test 8.

The maximum dynamic crush on the car was 38.9 inches at 108 milliseconds with a pitch angle of 9.4 degrees. Rebound of the Plymouth off the face of the Test Device caused the rear of the car to rotate approximately 2 inches counterclockwise from the barrier centerline. Rebound of the Plymouth from the initial impact point was 39 inches. The fixed Test Device structure was damaged due to the geometric aggressiveness of the Plymouth bumper, and failure of the attachment bolts of the vertical member. The extent of this damage, and resulting modifications will be discussed later in this report.

4.1.2 Moving Test Device Test

In the moving Test Device test, the Plymouth impacted the aluminum honeycomb modul at a closing speed of 70.0 mph, causing approximately 26.1 inches of static crush to the vehicle. The final speed of the Plymouth was -2.6 mph. The final speed of the Test Device was -3.0 mph, indicating the Test Device was pushed backwards by the car after impact due to the fact the car was 144 pounds heavier than the Test Device. The total velocity change to the car was 31.6 mph. The maximum dynamic crush on the car was 40.2 inches at 37 milliseconds and a pitch angle of 3.0 degrees.

Moving Test Device tests conducted to date have been adjusted to give similar change in velocity to comparable fixed Test Device tests. Upon impact, the Plymouth remained close to the area of impact while the Test Device was pushed backwards, stopping 23.3 feet from the car. There was no rotation of either vehicle and no damage to the Test Device structure.

Vehicle data, including all pre-test and post test measurements and summaries of vehicle accelerometer data, are discussed in Section 4.2. Test device data, including summaries of load cell, string potentiometer, accelerometer, strain gauge data, and honeycomb crush profiles, are discussed in Section 4.3. Occupant response data is discussed in Section 4.4.

4.2 VEHICLE STRUCTURAL RESPONSE

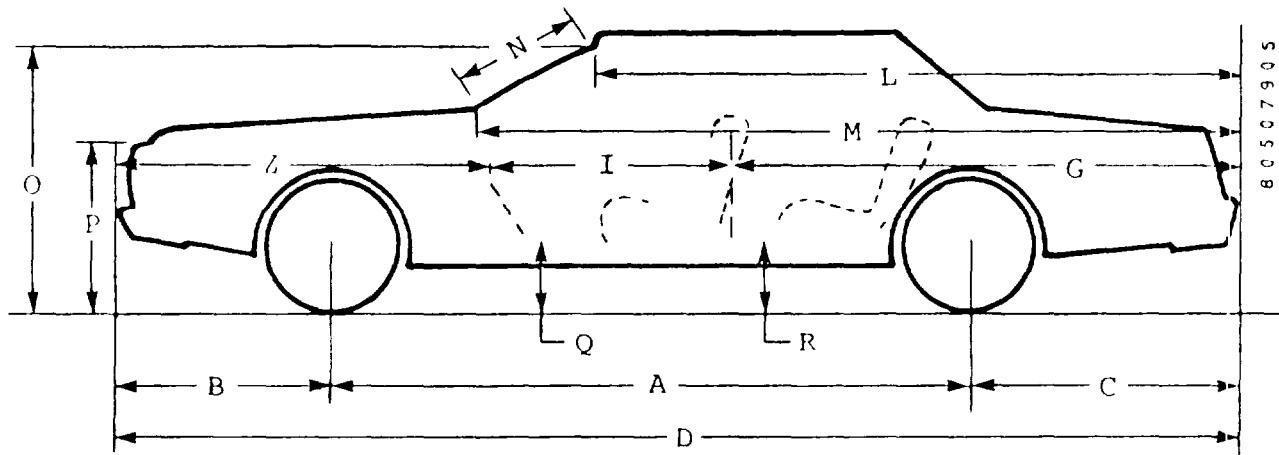

This section of the report presents data on the Plymouth's structural response to the collision with the fixed and moving Test Devices. This includes pre-test and post-test measurements made at selected locations on the vehicle, steering wheel displacements, vehicle exterior and interior profiles, and accelerometer data.

Static crush measurements of the Plymouth for both fixed and moving Test Device tests are shown in Table 4-8. Pre-test and post-test bumper match-ups are shown in Figures 4-5 through 4-8. In both tests, the car deformed uniformly with the flat surface of the Test Device. Since the closing speed for the moving Test Device test was selected to give the same change in energy (ΔE), most of the crush measurements were very similar for both tests. In both tests, the hood latch of the Plymouth failed, which did not allow the hood to aid in resisting the structural crush of the car.

Exterior profiles are given in Tables 4-9 and 4-10. Measurements for the frontal exterior profile of the Plymouth were made at three levels: the hood level, the bumper level, and a level between the hood and bumper level. In Test 7, the bumper of the Plymouth rotated down slightly from the force caused by the impact, while in Test 8, the bumper showed no rotation. The cars used in both tests contained bumper guards which were highly responsible for concentrated loads to be recorded by the load cells. In both tests the frontal crash was fairly flat across the face of the cars.

Vehicle interior intrusion profiles and steering wheel displacement values are given in Tables 4-11 through 4-14. Compartment intrusion is shown in Figures 4-9 through 4-12. In both tests, the dash panel remained attached to the frame of the car, but elongation of the seat belt allowed the occupants to come

*Reference for X, Y, Z measurements are the rear bumper (+ forward), vehicle centerline (+ right), and ground level (+ up), respectively.

into contact with the dash area. This caused large pulses to be seen by the occupant head accelerometers. In Test No. 8, the steering wheel rim was not bent by the left front occupant, resulting in smaller crash pulses to be seen on data from the driver's chest.

A summary of Plymouth accelerometer and string potentiometer data for both tests is given in Tables 4-14 through 4-19. Refer to Figure 3-1 for their locations in the vehicle. Compartment accelerometers and engine accelerometers were averaged to obtain a more representative picture of what was occurring at these locations. String potentiometer data was used to measure firewall intrusion in the occupant compartment. However, if the peak intrusion does not occur at the location where the measurement was taken, the readings could be low compared to the post-test static measurements.

In both tests, since the amount of crush was high, rotation of firewall and engine accelerometers (Nos. 4, 6, and 9) occurred, giving erroneous velocity and displacement peaks. In Test 8, the lower engine accelerometer (location 5) was lost due to a cut

cable. Data used in analysis used only data from the upper engine accelerometer (location 6). In addition, data from the accelerometer located on the vehicle front crossmember (location 7) was lost, also due to instrumentation failure during impact.

4.3 TEST DEVICE SUMMARY

This section of the report presents a summary of data gathered from the fixed and moving Test Devices. This includes summaries of load cell, string potentiometer, strain gauge, and accelerometer data, and post-test honeycomb profiles for both fixed and moving Test Device tests.

Post-test Test Device configurations for fixed and moving Test Device tests are shown in Figures 4-13 and 4-14.

Figure 4-13. Post-test Fixed Test Device Configuration - Test 7.

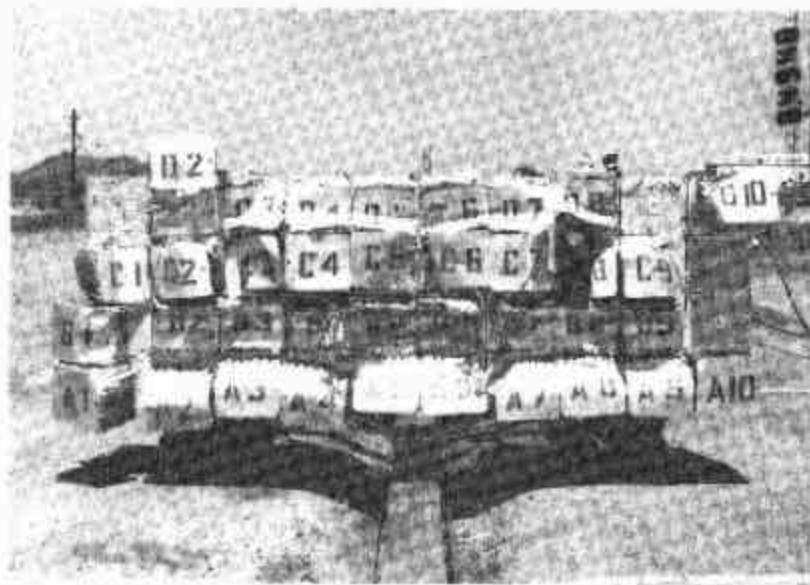

Figure 4-14. Post-test Moving Test Device Configuration - Test 8.

A summary of peak values of load cell data is shown in Table 4-20 for Test 7 and Table 4-21 for Test 8. These were the maximum measured forces for each load cell along with its corresponding time recorded during the event. Tables 4-22 and 4-23 present a summary of grouped load cell data for each test. The front face of the Test Device was divided into six areas of loading. These data show which areas of the car tended to be more aggressive. Load cell forces for individual load cells are shown in Figures 4-15 through 4-22. These plots also show the relative lateral symmetry of car data recorded with the Test Device face. Some loads may have been lost during the period 25-50 msec in Test 7 and 24-40 msec in Test 8, due to load cell contact with the backing plate (B5, B6, B9).

A load cell distribution at selected time intervals for the car/Test Device interface for each test is shown in figures 4-23 through 4-28. These values are shown for forces over 1,000 pounds at a particular time segment. Any location with a value below 1,000 pounds was not considered an aggressive part of the car at that particular time frame. Calcomp plots of all load cell data by columns and grouped load cell summations are shown in Appendix B for Test 7 and Appendix C for Test 8.

In the fixed Test Device test, the maximum total load cell force was 77,740 pounds at 34 msec after impact and the maximum individual load cell force recorded was 11,300 pounds on module B⁺ at 87 msec.

The fixed Test Device structure was damaged when the bumper of the car wedged between Rows B and C. This caused one aluminum

plates of the Test Device to undergo high torquing forces which overstressed the attachment bolts holding the horizontal beams to the vertical member of the Test Device (see Figure 4-6). Post-test inspection of the Test Device fixture showed the 5/8-inch grade nine attachment bolts of Row B pulled completely out of the vertical member. Attachment bolts on Rows C and D were bent upward due to the failure of Row B. The aggressive areas of the

LEGEND:

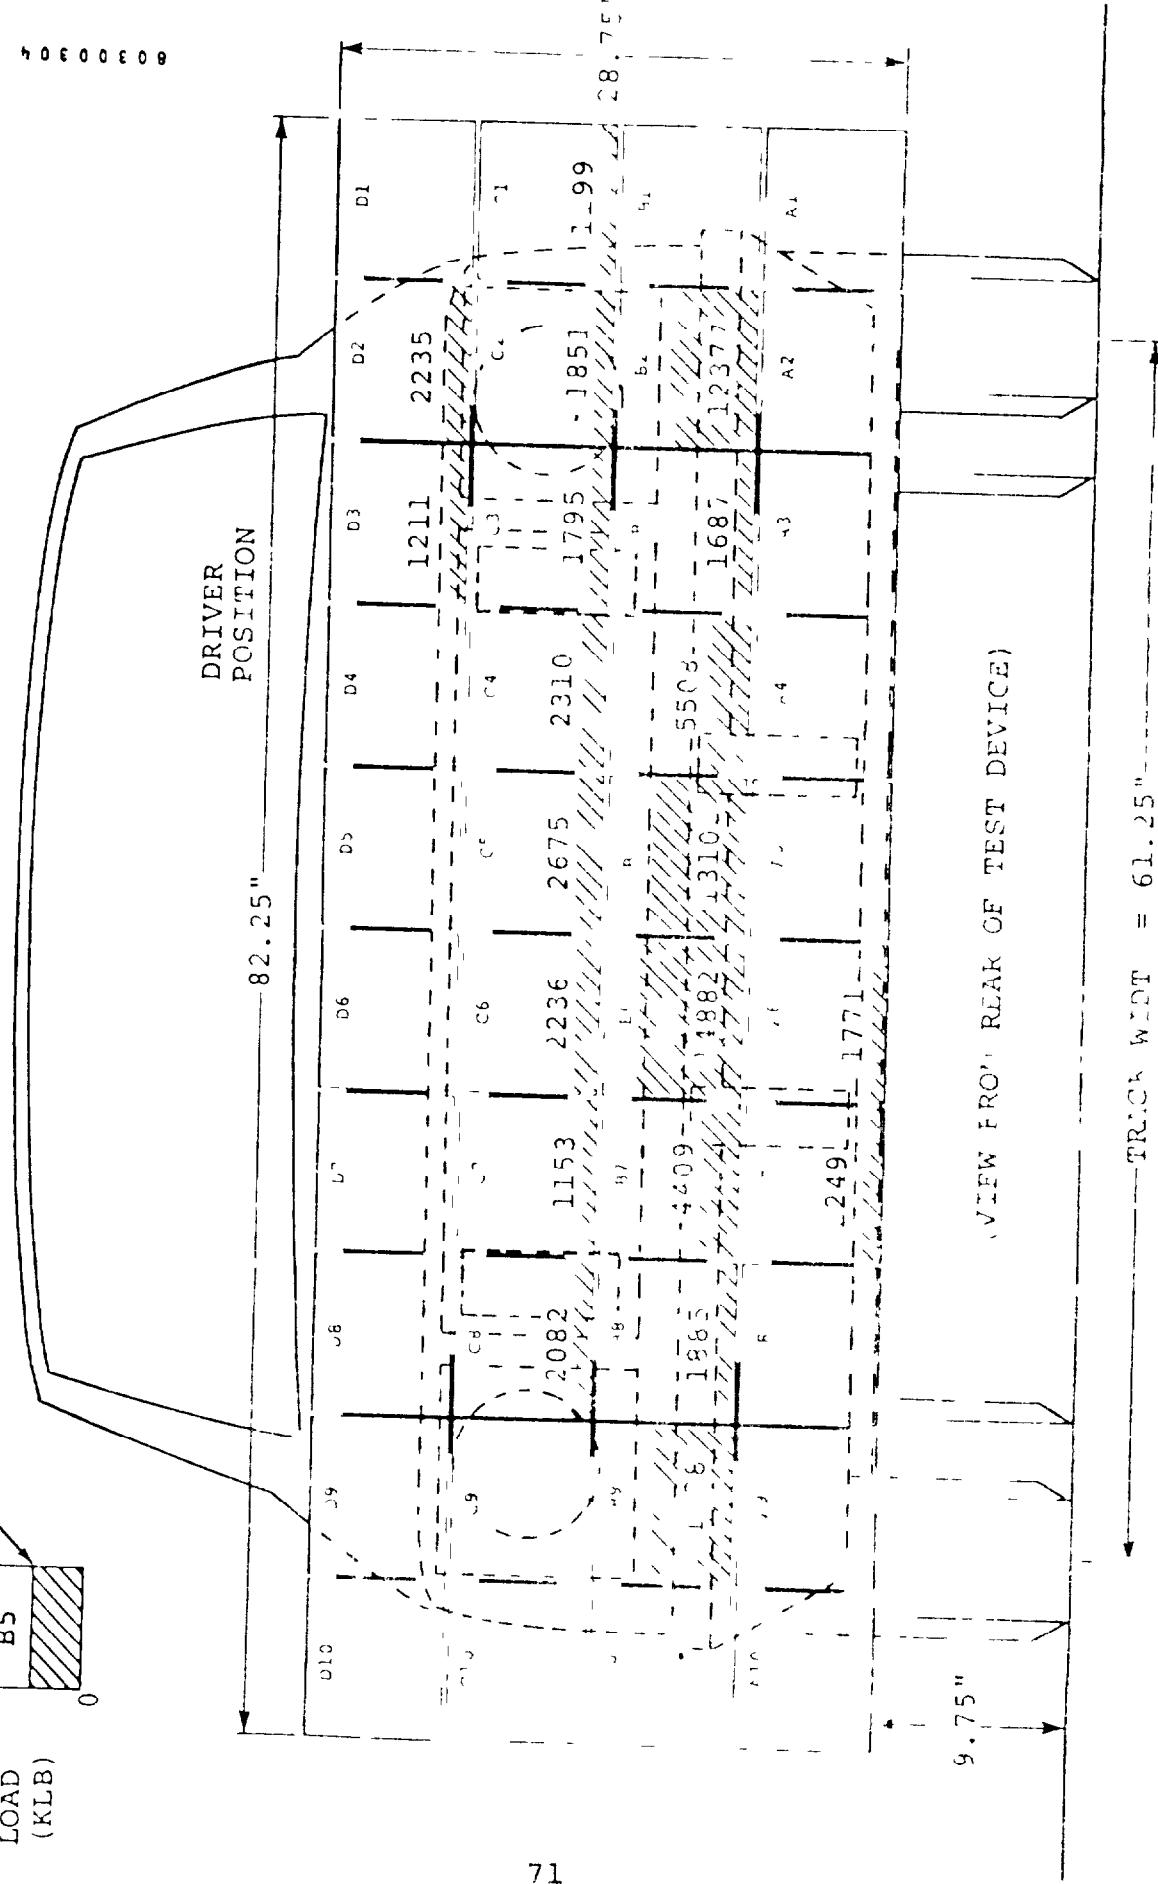

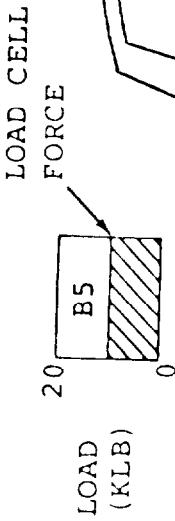

Figure 4-28. 1975 Plymouth Fury, during Test Device Load Distribution at 36 msec.

car appeared to be the bumper/engine area, bumper guards, hood line, and outer edges of the front of the car. Loads measured were not all recorded due to bottoming out of some Row B mounting plates, and load lost in damaging the Test Device Structure.

For the moving Test Device test, the total load cell force was 98,370 pounds* at 23 msec after impact and the maximum individual load cell force recorded was 15,400 pounds on module B6 at 45 msec. Due to the damage done to the fixed Test Device structure, modifications were made to the moving Test Device to aid in strengthening its structure. This consisted of the following modifications done before Test 8:

- Welding 4" x 4" x 1/4" steel plate to back of horizontal beams at the point of attachment to the vertical beam to prevent vertical rotation.
- Bolting on to front of the four horizontal beams a 25-3/4" x 2-1/2" x 1/4" vertical stiffener to each side of the Test Device to prevent vertical rotation.
- Redrilling and tapping the vertical beam on the Test Device from 5/8" to 3/4" to give the attachment bolts more thread support.
- Due to localized bending of the material behind two of the load cells on Row B horizontal beam, the beam was exchanged with the Row A horizontal beam and reattached.

Accelerometer data recorded from the moving Test Device are given in Table 4-24. Accelerometers were located on the right and left frame members of the Test Device and were averaged to give acceleration, velocity, and displacement curves for the Test Device. These data were used in comparing the total force from both load cell and accelerometer data for both tests, which are presented in Tables 4-25 and 4-26.

*The actual force may have reached 158,000 pounds (see Figure 4-33).

TABLE 4-24. SUMMARY OF MOVING TEST DEVICE ACCELEROMETER DATA

String potentiometer and strain gauge data for each test are presented in Tables 4-27 through 4-30. String potentiometers were placed at selected locations on the Test Device to measure dynamic crush of the honeycomb. The displacement measured on the honeycomb is an indication of the dynamic crush at the particular point on the honeycomb modules, in all cases, the center of the module. Since the vehicle striking the honeycomb is not a uniformly flat surface, the crush measurement at the center of the module is not

necessarily a true indication of crush to the remainder of the aluminum honeycomb. Strain gauge data was used to see how typical loads would affect key structural members of the Test Device.

Figure 4-29 shows typical strain gauge curves for the most highly stressed member. The maximum allowable (yield) strain was 0.350 μin./in., which is quite adequate for the strain data recorded for this test.

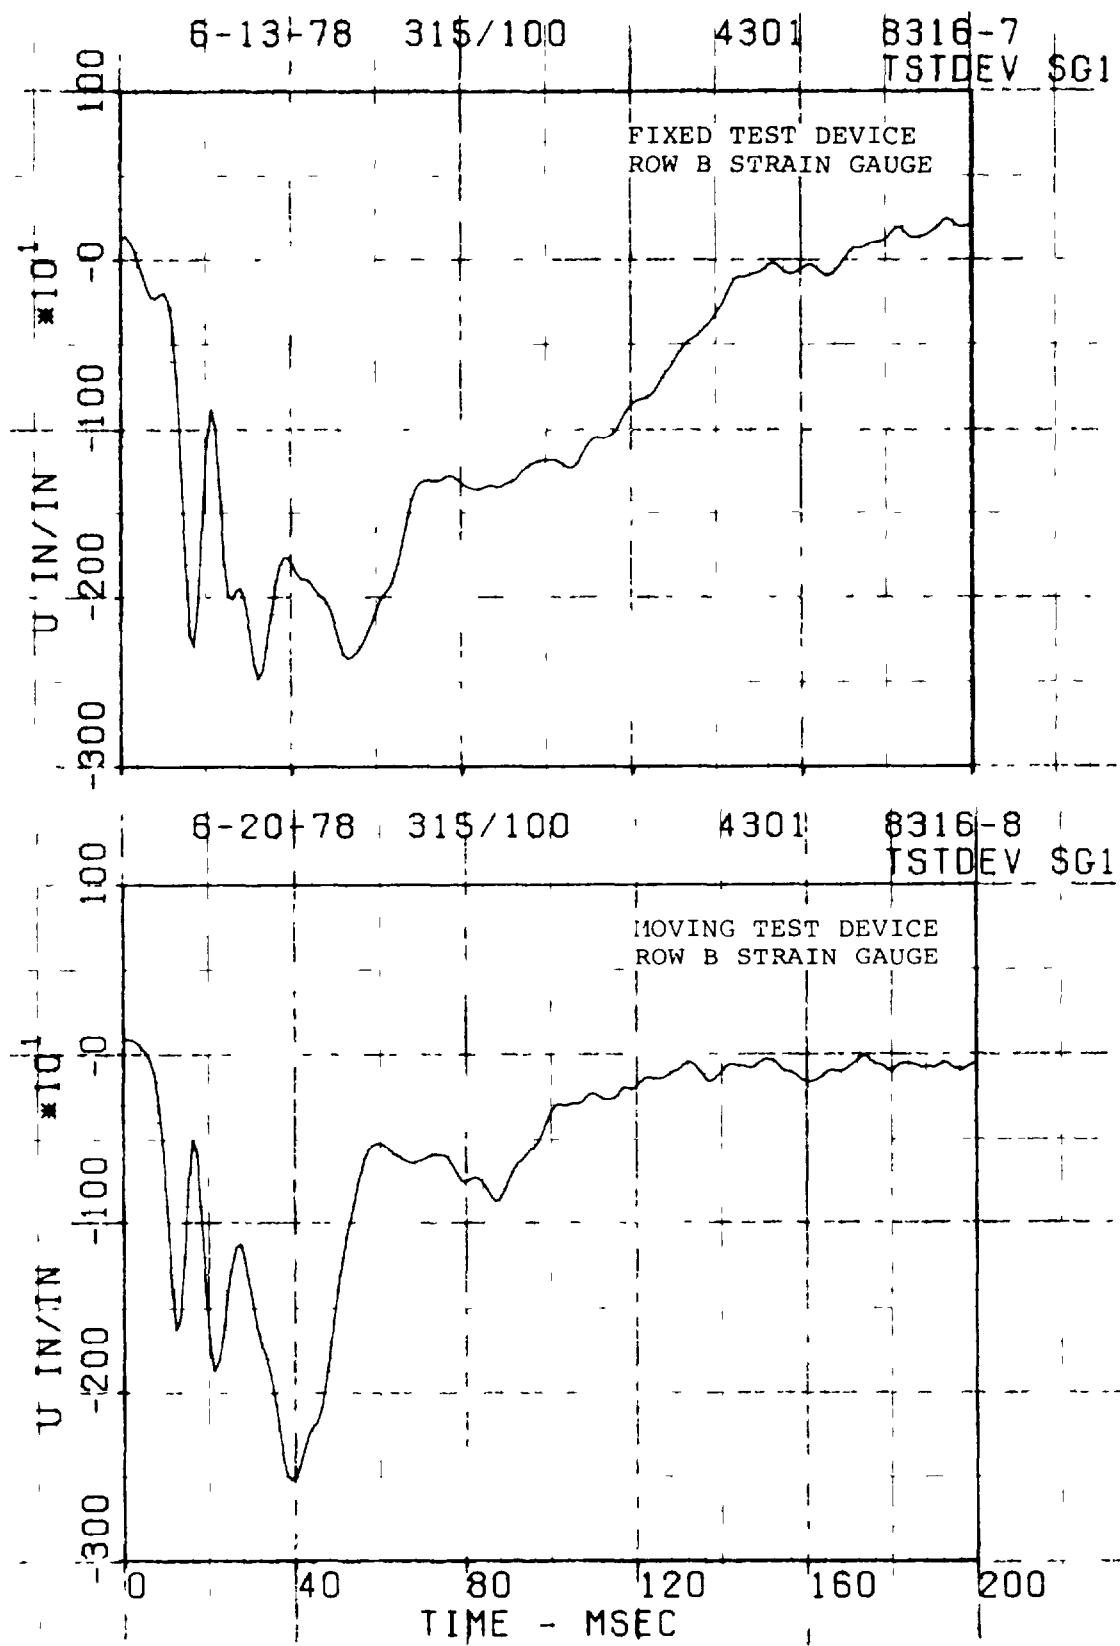

Figure 4-29. Strain Gauge Data - Row B Horizontal Beam.

The aluminum honeycomb crush profiles for fixed and moving Test Device tests are presented in Tables 4-31 and 4-32. Refer to Figures 4-13 and 4-14 for a view of the post-test configuration of the honeycomb. In Test 7, since the horizontal beams which the aluminum honeycomb attaches to were deformed, the entire load transmitted by the Plymouth was not reflected in the crush of the honeycomb. Modules D1 and D10 were sheared off the Test Device face by the car on impact. In Test 8, crush of the honeycomb was more consistent to what should have been observed in Test 7. Modules D1, D9, B10, and C10 were sheared off by the car on impact. In both tests, the main areas responsible for crush were the bumper/engine, bumper guards, hood line, and the front edges of each fender near the headlights.

A comparison of dynamic crush from accelerometer data and film analysis is shown in Figures 4-30 and 4-31. Since the vehicle does not act as a rigid body during the test, and vehicle accelerometer data is only representative of one location in an elastic body (at the B-pillar of the car), this data tends to be consistently higher than the data from film analysis. The data from film analysis is considered more accurate since a visual measurement of crush versus time is taken.

Total load cell force data and calculated inertia force from accelerometer data are shown in Figure 4-32 for Test 7 and Figure 4-33 for Test 8. Since the fixed Test Device is not instrumented with accelerometers, the inertia force was calculated using the car data, namely, the vehicle's averaged accelerometer data along with its test weight. In this case, the engine and car mass were considered as separate masses, since their dynamics during the

event are different. The total inertia force was calculated by using $F = ma$ for the engine and car mass separately, and adding the two together. In the moving Test Device test, the inertia force can also be calculated using accelerometer data from the Test Device. In this case, the Test Device test is considered a rigid body. Figure 4-34 shows the load cell force-deflection characteristics for both tests. The vehicle rate of stiffness as load is applied is given in Table 4-33.

Car interior intrusion is plotted against exterior dynamic crush of the vehicle in Figures 4-35 through 4-37. Dynamic interior crush was measured by means of a string potentiometer located along the centerline of the vehicle. A difficulty sometimes occurs during impact when outside influences interfere with the displacement of the string potentiometer, causing misleading data.

A crash pulse may be monitored on the Test Device face to determine the "hard" points on the vehicle. Figures 4-38 and 4-39 show where on the Test Device face the centroid of the total load cell force was acting, as a function of time.

4.4 OCCUPANT KINEMATICS

This section of the report presents the results of dummy response during peak values for each occupant's head, chest, and femur, restraint survival distance, and restraint system summaries.

In evaluating occupant response data, it must be remembered that, because of the high crash speeds, pulses measured by each occupant are very high and may exceed FMVSS 208 Standards. Figures 4-40 through 4-47 show pre-test and post-test configurations of the occupant for each test. A summary of occupant response data is presented in Table 4-34 with restraint system data presented in Table 4-35.

In both tests, the left front occupant's head and chest made contact with the steering wheel and dash panel. Compartment intrusion in the Plymouth was less than in previous tests, resulting in lower occupant responses. The driver's head in Test 7 had a maximum displacement relative to ground of 84.4 inches at $t = 200$ msec, while in Test 8, the maximum displacement was 50.8 at $t = 120$ msec. Post-test observations showed the driver femurs both made contact with the knee bolsters, causing damage to that area. In both tests, the driver's chest struck the steering wheel hub, which showed little sign of yielding and caused high acceleration values to appear.

The right front passenger's head in the Plymouth made contact with the dash panel. Post-test observations showed that the knees struck the glove compartment area, leaving signs of deformation to that area. The occupant compartment in both tests showed some signs of intrusion, but it was less severe than in other tests. The passenger's chest loads were mainly caused by the shoulder belt restraint system. No visible contact was made with the passenger's chest in the occupant compartment.

*3-msec clip.

Restraint Survival Distance (RSD) criteria is presented in Table 4-36. This value was used in efforts to determine relative vehicle crashworthiness. Values in this table reflect RSD values with and without a 7-millisecond shift. The shift is to account for crush of the honeycomb on the test device. The vehicle compartment deceleration pulse and restraint system pulse were used

to compare available compartment space with the space necessary to decelerate the occupant. A critical element in calculating this value is the relative positioning of the dummy in the occupant compartment. Figures 4-48 through 4-51 show the pre-test and post-test occupant compartments for each test. Refer to Appendix D for an explanation of the methodology used to determine RSD values.

5.0 TEST FACILITIES AND EQUIPMENT

5.1 GENERAL

The impact tests in this program were conducted at the Monorail Impact Facility, shown in Figure 2-1. The barrier impact and midrange impact sites were used for the fixed Test Device/vehicle and moving Test Device/vehicle tests, respectively.

Table 5-1 describes the test equipment and its function as it applies to the test parameters.

TABLE 5-1. TEST EQUIPMENT LIST AND FUNCTION

Item	Manufacturer	Model	Purpose
Timing Trap	Dynamic Science	None	Determines impact speed by furnishing a start and stop signal to recording oscilloscope.
Oscilloscope	Bell and Howell	5-134	Records time, start and stop signals from timing traps, cable drum drive rom, and impact switch.
Speed Control	Dynamic Science	None	Provides control of cable drive drum.
Beam Scales	Western	WP2000	Used to determine vehicle test weight.
High-speed Motion Picture Cameras	Photsonics	16-1L	Used to film overhead, barrier, pit, and on-board film coverage as required.
Motion Picture Camera	Bolex	H-16	Pairing and documentation.
Still Camera	Kowa	6	Documentation photo coverage.

TABLE 5-1. TEST EQUIPMENT LIST AND FUNCTION (CONTD)

<u>Item</u>	<u>Manufacturer</u>	<u>Model</u>	<u>Purpose</u>
100 and 1000 Hz Time Code Generators	Dynamic Science	None	Furnish timing signal for high-speed cameras and a 1 millisecond timing for velocity determination.
Stop Watch	Brietling	None	Time for collection of fuel leak samples.
Containers	-	-	Collection for fuel leak samples.
Graduated Cylinder	Kimes	-	Fuel volume measurement.
Calibrated Steel Rule	Starret	48 in.	Precision measurement of velocity trap spacing.
Anthropomorphic Dummies	Alderson	(GFE)	To ballast the vehicle and to gather occupant response data.
Dummy and Vehicle Accelerometers	Endevco	7233C	Measures acceleration.
String Pots	Celesco	PT-101- 15	Measures displacement.
12.5K Load Cells	Interface	1210 FS 1210 LT	Force on honeycomb modules.
3K Load Cell GSE (Femur)	GSE	2435	Determines femur load forces.
3500-pound Load Cell (Belt)	LeBow	3419	Measures belt loads.
F.M. Multiplexor Tape Recorder	Sangamo	Sabre III	Records instrumentation signals.
Oscillograph	Bell and Howell	5-134	Records real-time quick-look data.
Signal Conditioner	Ectron	M140	Conditions instrument output signal for recording.

5.2 FACILITY AND EQUIPMENT DESCRIPTION

The following paragraphs briefly describe the track facility and equipment, their function, and mode of operation.

5.2.1 Test Track and Guidance System

The test track consists of 1,200 feet of asphalt pavement ($SN = 75 \pm 5$), 14 feet in width. The length allows sufficient acceleration distance to accommodate impact speeds in excess of 60 mph with sufficient distance remaining to abort the test if necessary. Guidance for the test vehicle is provided by a sliding shoe attached to the vehicle. The sliding shoe rides on the monorail embedded in the test track. Prior to impact, the shoe is mechanically released from the test vehicle.

5.2.2 Tow System and Velocity Control

The tow system consists of a drum-driven endless cable powered by a pair of 390-cubic-inch engines driven in tandem driving a modified three-speed C-6 automatic truck transmission. The tow system can propel a 6,000-pound vehicle into the fixed barrier at 75 mph or two 4,000-pound vehicles into each other at a closing speed of 90 mph. Velocity control is achieved through a manually controlled throttle system. A visual readout of speed versus distance is provided and compared with the "ideal" curve. Velocity control under ± 0.5 mph is realizable down to 10 mph and ± 2.0 percent down to zero mph.

5.2.3 Abort System

Automatic abort capability is provided through the vehicle service brakes which are actuated by releasing high-pressure air into the hydraulic system. Abort criteria consists of vehicle speed, data acquisition and instrumentation system readiness, and

stability of the vehicle on the test track. The first two criteria are automatically monitored by the test control system while the third criterion is visually monitored by the test conductor. Manual abort provisions are available to the test conductor. Upon verifying vehicle speed, the test control system automatically deactivates the abort system to preclude an inadvertent test abort immediately prior to impact.

5.2.4 Master Control System

The master control system used for impact test's controls and monitors all primary system functions that must operate throughout a predetermined interval during a test. This includes the starting and stopping of the FM multiplexer tape recorder, high-speed cameras, and oscillograph, and the control of the power winch which propels the test vehicle. The operation of the various devices is confirmed, including vehicle velocity and tape recorder speed synchronization, before it passes through a "commit" window. When the vehicle is committed, the abort system is disarmed, preventing an accidental abort after the point of no return is reached.

Any system malfunction, including improper vehicle velocity up to the commit window, generates an abort. The control system uses the pulse output from the IRIG time base generator as a clock with a manual push button defining time zero. The logic circuits compare pulse counts from time zero to preset values dialed in at the control panel. As each control circuit gets an equal comparison, that circuit is turned off. If the self-test circuit does not verify, the abort system is automatically activated. After a successful vehicle test, the last control circuit shuts the entire system down. The manual backup control system provides the test conductor with the option of manually aborting the test if the need arises.

5.2.5 Fixed Impact Barrier

The basic fixed impact barrier consists of a reinforced concrete structure, 6 feet high, 6 feet thick, and 12 feet wide, weighing approximately 100,000 pounds and complying with SAE J850. This barrier can be fitted with various models including a flat-faced barrier adjustable to angles up to 45 degrees, as well as a pole barrier. This barrier system conforms to the definition of a "fixed collision barrier" as defined in Federal Register, Vol. 35, No. 135, page 11242 (July 14, 1970).

A camera pit is located immediately in front of the impact barrier and is 6 feet wide, 8 feet deep, and 20 feet long. The pit is covered with a metal grid which supports the vehicle as it passes over, yet allows photographing of the vehicle underside when required. Electrical outlets are provided for powering floodlights and high-speed cameras. A fixed overhead camera tower cantilevered over the barrier test site provides over-site photography.

5.2.6 Midrange Impact Site

The midrange test site consists of a 40-foot by 60-foot asphalt pad. Centrally located within this area is a camera pit constructed of reinforced concrete which is 6 feet wide, 8 feet deep, and 24 feet long. A metal grid covers the camera pit, allowing photographs to be taken of the vehicle underside. A movable overhead camera tower is provided for over-site photography.

5.2.7 High-speed Photography

Six high-speed 16mm cameras with lead ball marks and one panning camera are used for photographic test documentation. Precise field of view monitoring is accomplished by bore sighting with the vehicle at the impact site prior to the test.

APPENDIX A

CAR-TO-TEST DEVICE CRASH ANALYSIS

Prepared by:

Jack Beharrell
Jack Beharrell

Special Projects
Department
5/8/78

1.0 DETERMINATION OF EQUIVALENT CLOSING SPEED FOR MOVING BARRIER COLLISION

Moving Barrier Collision:

$$\Delta V_A = \frac{W_B}{(W_A + W_B)} [V_A(0) - V_B(0)] - \frac{V_B}{(W_A + W_B)} [\Delta V(0)] \quad (1)$$

where ΔV_A = velocity change of vehicle A in moving barrier impact (mph)

W_A, W_B = weight of vehicles A and B, respectively (lb)

$V_A(0), V_B(0)$ = initial velocities of vehicles A and B, respectively (mph)

$\Delta V(0)$ = initial closing velocity (mph)

Fixed Barrier Collision:

$$\Delta V'_A = V_A'(0) \quad (2)$$

where $\Delta V'_A$ = velocity change in fixed barrier impact (mph)

$V_A'(0)$ = initial velocity of vehicle A (mph)

- Equality Conditions

The desired equality condition (the same total velocity change in the moving barrier and fixed barrier impact) implies

$$\Delta V_A = V_A' \quad (3)$$

Therefore Equations (1) and (2) result in the following condition for the "equivalent" to an impact speed for the moving barrier test:

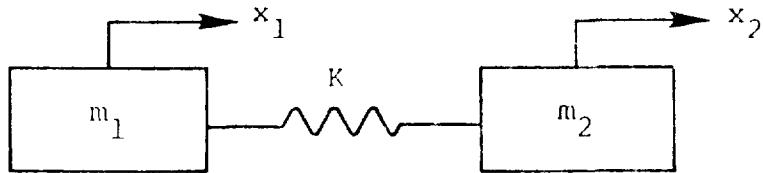

$$\Delta V(0) = V_A'(0) \left[\frac{W_B}{(W_A + W_B)} \right] \quad (4)$$

For $W_B = 4000$ lb, and $V_A'(0) = 10$ mph, (4) becomes

$$\Delta V(0) = 10 \left[\frac{4000}{(W_A + 4000)} \right] \quad (5)$$

2.0 DERIVATION OF EQUATIONS OF MOTION

The vehicle-barrier impact was modeled as a system of two masses connected by a linear spring. m_2 represents the mass of the barrier test device; m_1 that of the car.

The displacements x_1 and x_2 are measured from the positions of static equilibrium. The equations of motion are:

$$m_1 \ddot{x}_1 + K (x_1 - x_2) = 0 \quad (1)$$

$$m_2 \ddot{x}_2 + K (x_2 - x_1) = 0 \quad (2)$$

Substitution of the solutions

$$x_1 = x_1 \cos \omega_n t, \quad x_2 = x_2 \cos \omega_n t$$

leads to the normal mode shape

$$\rho = \frac{x_2}{x_1} = \frac{K}{K - m_2 \omega_n^2} = \frac{-m_1 \omega_n^2 + K}{K} \quad (3)$$

The characteristic equation for the system has the solutions

$$\omega_{n_1}^2 = 0, \quad \omega_n^2 = K \left(\frac{m_1 + m_2}{m_1 m_2} \right) \quad (4)$$

The solution $\omega_n = 0$ represents a lateral displacement of the system with no spring compression or extension.

The general solution of the equations (1) and (2) is of the form

$$x_1 = B_1 + B_2 t + B_3 \cos \omega_{n_2} t + B_4 \sin \omega_{n_2} t$$

$$x_2 = B_1 + B_2 t + B_3 \rho \cos \omega_{n_2} t + B_4 \rho \sin \omega_{n_2} t \quad (5)$$

where $B_1 = \frac{x_{20} - \rho x_{10}}{1 - \rho}$, $B_3 = \frac{x_{10} - x_{20}}{1 - \rho}$

$$B_2 = \frac{v_{20} - \rho v_{10}}{1 - \rho}, \quad B_4 = \frac{v_{10} - v_{20}}{(1 - \rho)^2} \quad (6)$$

x_{10} , v_{10} , x_{20} , v_{20} are the initial displacements and velocities of the vehicle and barrier, respectively. We may set $x_{10} = x_{20} = 0$; then $B_1 = B_3 = 0$. Differentiation of (5) with respect to time and substitution of (6) leads to the following relations for the displacements, velocities, and accelerations of the car and barrier:

$$x_1 = \left(\frac{v_{20} - \rho v_{10}}{1 - \rho} \right) t + \left(\frac{v_{10} - v_{20}}{(1 - \rho)^2} \right) \frac{t}{\omega_{n_2}} \sin \omega_{n_2} t$$

$$x_2 = \left(\frac{v_{20} - \rho v_{10}}{1 - \rho} \right) t + \left(\frac{v_{10} - v_{20}}{(1 - \rho)^2} \right) \frac{t^2}{\omega_{n_2}^2} \sin \omega_{n_2} t \quad (7)$$

$$\begin{aligned}\dot{x}_1 &= \frac{v_{20} - \rho v_{10}}{1 - \rho} + \left(\frac{v_{10} - v_{20}}{1 - \rho} \right) \cos \omega_{n_2} t \\ \dot{x}_2 &= \frac{v_{20} - \rho v_{10}}{1 - \rho} + \left(\frac{v_{10} - v_{20}}{1 - \rho} \right) \rho \cos \omega_{n_2} t\end{aligned}\quad (8)$$

$$\begin{aligned}\ddot{x}_1 &= - \left(\frac{v_{10} - v_{20}}{1 - \rho} \right) \omega_{n_2} \sin \omega_{n_2} t \\ \ddot{x}_2 &= - \left(\frac{v_{10} - v_{20}}{1 - \rho} \right) \rho \omega_{n_2} \sin \omega_{n_2} t\end{aligned}\quad (9)$$

Using equations (3) and (4), the quantities ρ and $1-\rho$ become:

$$\rho = \frac{m_1}{m_2}$$

$$1-\rho = \frac{m_1 + m_2}{m_2} \quad (10)$$

For the fixed barrier case, the above equations for ρ and $1-\rho$ reduce to $\rho=0$, $1-\rho=1$, $\omega_n = (\frac{K}{m_1})^{1/2}$; then x , \dot{x} , \ddot{x} become: ($m_2 = \infty$, $v_{20} = 0$)

$$\begin{aligned}x_1 &= v_{10} \left(\frac{m_1}{K} \right)^{1/2} \sin \left(\frac{K}{m_1} \right)^{1/2} t \\ x_2 &= 0\end{aligned}\quad (11)$$

$$\begin{aligned}\dot{x}_1 &= v_{10} \cos \left(\frac{K}{m_1} \right)^{1/2} t \\ \dot{x}_2 &= 0\end{aligned}\quad (12)$$

$$x_1 = -v_{10} \left(\frac{K}{m_1}\right)^{1/2} \sin \left(\frac{K}{m_1}\right)^{1/2} t$$

$$\ddot{x}_2 = 0$$

(13)

3.0 CALCULATION OF EQUIVALENT CLOSING VELOCITIES FOR SELECTED CRASH PARAMETERS

Maintaining selected crash parameters constant for both the fixed barrier and the moving barrier conditions, equivalent vehicle-barrier closing velocities were calculated. The applicable equations and some equivalent closing speeds are summarized in Table 1. Table 2 presents a summary of the times of occurrence for selected vehicle parameters. It should be noted that the closing speeds may be obtained by adjusting either the vehicle speed, the barrier speed, or both.

P is the parameter to be maintained constant.

Barred quantities refer to moving barrier case.

(1) P: Initial relative velocity of vehicle and barrier.

Fixed barrier case:

$$\text{Initial relative velocity} = v_{10} - v_0 = v_{10}$$

Moving barrier case:

$$\text{Initial relative velocity} = \bar{v}_{10} - \bar{v}_{20}$$

The equivalent closing speed is then given by the equality:

$$\bar{v}_{10} - \bar{v}_{20} = v_{10}$$

(2) P: Maximum velocity change of vehicle.
 Velocity change = $\Delta V = v_{10} - x_1$ final.

$$\therefore \Delta V = v_{10} - \left(\frac{v_{20} - \rho v_{10}}{1 - \rho} \right)$$

$$= \frac{v_{10} - v_{20}}{1 - \rho}$$

Fixed barrier case:

$$\Delta V = v_{10}$$

Moving barrier case:

$$\bar{\Delta V} = \frac{(v_{10} - v_{20})}{(m_1 + m_2)} m_2$$

For $\Delta V = \bar{\Delta V}$

$$\bar{v}_{10} - \bar{v}_{20} = \left(\frac{m_1 + m_2}{m_2} \right) v_{10}$$

(3) P: Maximum momentum change of vehicle.

The condition here is

$$m_1 \Delta V = m_1 \bar{\Delta V}$$

Therefore the result is the same as in (2):

$$\bar{v}_{10} - \bar{v}_{20} = \left(\frac{m_1 + m_2}{m_2} \right) v_{10}$$

- (4) P: Maximum passenger compartment acceleration (deceleration)

Fixed barrier case:

From equation (13)

$$|x_1|_{\max} = v_{10} \left(\frac{k}{m_1} \right)^{1/2}$$

Moving barrier case:

From equation (9)

$$|\ddot{x}_1|_{\max} = (\bar{v}_{10} - \bar{v}_{20}) \left[k \frac{(m_1 + m_2)}{m_1 w} \right]^{1/2} \left(\frac{m_2}{m_1 + m_2} \right)$$

Equating $|x_1|_{\max}$ and $|\ddot{x}_1|_{\max}$ gives

$$\bar{v}_{10} - \bar{v}_{20} = \left(\frac{m_1 + m_2}{m_2} \right)^{1/2} v_{10}$$

- (5) P: Maximum spring crush

$$\text{Maximum spring crush} = |x_1 - x_2|_{\max}$$

$$= \frac{v_{10} - v_{20}}{\omega_n}$$

Fixed barrier case:

$$\text{Maximum crush} = v_{10} \left(\frac{1}{k} \right)^{1/2}$$

Moving barrier case:

$$\text{Maximum crush} = (\bar{v}_{10} - \bar{v}_{20}) \left(\frac{m_1 m_2}{K(m_1 + m_2)} \right)^{1/2}$$

The equivalent closing speed for equality of maximum spring crush is then

$$\bar{v}_{10} - \bar{v}_{20} = \left(\frac{m_1 + m_2}{m_2} \right)^{1/2} v_{10}$$

(6) P: Maximum energy absorbed by vehicle.

This calculation is based upon the assumption that all the energy of spring compression represents energy absorbed by the vehicle.

$$\text{Energy absorbed} = \frac{1}{2} K (x_1 - x_2)^2$$

Maximum energy absorbed is then given by the quantity

$$\frac{1}{2} K \left[\left(\frac{v_{10} - v_{20}}{\omega_n} \right)^2 \right]$$

Fixed barrier case:

$$\text{Maximum energy absorbed} = \frac{1}{2} K \left[v_{10} \sqrt{\frac{m_L}{K}} \right]^2$$

Moving barrier case:

$$\text{Maximum energy absorbed} = \frac{1}{2} K \left[\left(\frac{\bar{v}_{10} - \bar{v}_{20}}{\left[K(m_1 + m_2) \right]^{1/2}} \right)^2 \right]$$

Equivalent closing speed for equal maximum energy absorption is then:

$$\bar{v}_{10} - \bar{v}_{20} = \left(\frac{m_1 + m_2}{m_2} \right)^{1/2} v_{10}$$

3.1 TIME OF OCCURRENCE OF MAXIMUM VELOCITY AND MOMENTUM CHANGE,
MAXIMUM ACCELERATION, MAXIMUM SPRING CRUSH, AND MAXIMUM
ENERGY ABSORPTION

From equations (7), (8), and (9), it is apparent that this time of occurrence is given by

$$_n t = \frac{l}{2}$$

$$\text{or } t = \frac{\pi}{2\omega_n}$$

Fixed barrier case ($t = T$)

$$\Gamma = \frac{1}{2} \left(\frac{m_1}{K} \right)^{1/2}$$

Moving barrier case ($t = \tau$)

$$= \frac{\pi}{2} \left[\frac{m_1 m_2}{K(m_1 + m_2)} \right]^{1/2}$$

$$\text{The ratio } \frac{\tau}{T} = \left(\frac{m_2}{m_1 + m_2} \right)^{1/2}$$

Values for this ratio for several cars are given in Table 2.

4.0 DYNAMIC TEST CONDITIONS AND VEHICLE DATA

4.1 DEFINITIONS OF SYMBOLS

$w_2 (m_2)$ = weight (mass) of barrier test device.

$w_1 (m_1)$ = weight (mass) of vehicle.

v_{10} = initial velocity of vehicle for fixed barrier case.

\bar{v}_{10} = initial velocity of vehicle for moving barrier case

\bar{v}_{20} = initial velocity of moving barrier.

K = spring constant of vehicle crush structure.
 T = time of occurrence of vehicle parameter maximum (fixed barrier case).
 τ = time of occurrence of vehicle parameter (moving barrier case).
 ρ = mode shape.
 ω_n = natural frequency of system.

4.2 TEST CONDITIONS

$w_2 = 4000$ pounds (moving barrier)

$v_{20} = 0$

$w_2 = \infty$ (fixed barrier)

4.3 VEHICLE DATA

<u>Vehicle</u>	<u>Weight (lb)</u>	<u>Velocity V_{10} Fixed Barrier Condition (mph)</u>
Honda	2200	40

APPENDIX D

CALCULATION OF RESTRAINT SURVIVAL DISTANCE (NSD)

Prepared by:

Jerry Beharrell
Jack Beharrell
Analysis Engineer
Special Projects Department
Mar 8, 1978

APPENDIX D

CALCULATION OF RESTRAINT SURVIVAL DISTANCE (RSD)

1.0 METHODOLOGY FOR CALCULATION OF RSD

1.1 INTRODUCTION

A hypothetical air bag restraint system force-deflection characteristic is used in conjunction with barrier crash test results to calculate a relative crashworthiness parameter, the Restraint Survival Distance (RSD).

The RSD involves the occupant stroking distance (which includes the available vehicle interior space, plus some portion of the vehicle front structure crush which provides occupant ride-down). The degree of vehicle structural ride-down is determined by the combination of the vehicle crash pulse characteristics and the restraint system force deflection properties.

1.2 DETERMINATION OF RSD

The Restraint Survival Distance (RSD) is determined from the following relation:

$$RSD = AID - (D_p - D_c) (t = t^*)$$

where: AID is the available interior occupant stroke distance based on vehicle interior dimension

t^* is the time at which the occupant velocity equals compartment velocity

D_p is the absolute displacement of the occupant from initial crash impact until t^*

D_c is the absolute displacement of the vehicle compartment from initial impact to t^* . This is the amount determined from longitudinal vehicle acceleration data at positions (1) and (2) for the driver's side airbag, respectively (Figure D-1).

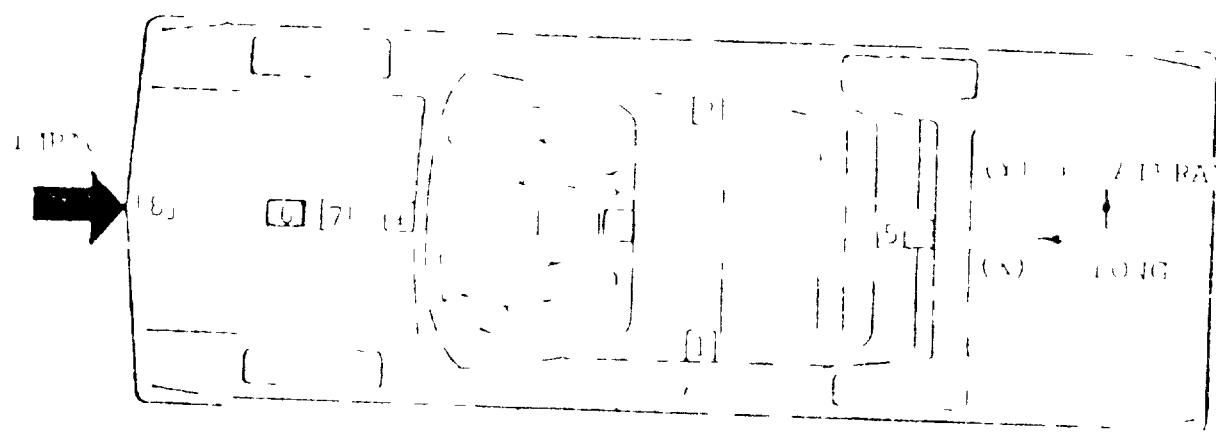

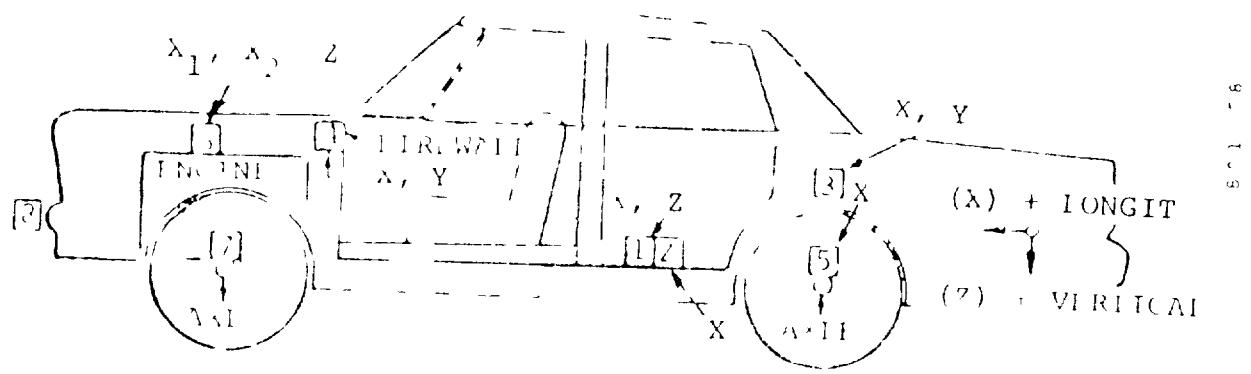

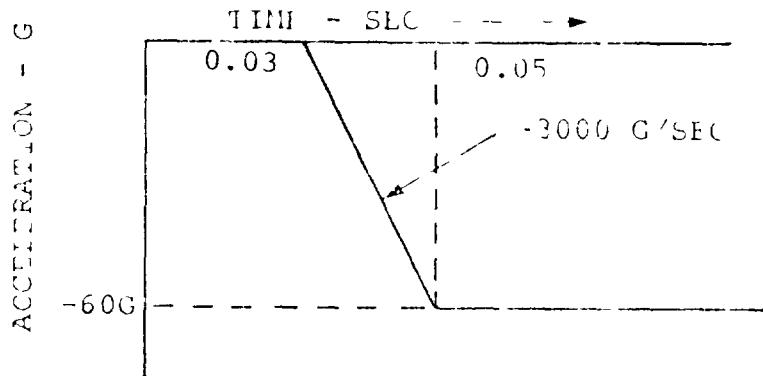

Figure D-1.

The absolute displacement of the occupant (ω_p) is determined assuming the following restraint system acceleration pulse (hypothetical air bag system)

Integrating this pulse from 0 to t^* gives the occupant velocity history

$$\dot{\omega}_p = V_1 + 43.47 + 2898t^* - 48300t^{*^2} \quad (.03 \leq t^* \leq .05) \quad (\text{ft/sec})$$

$$\dot{\omega}_p = V_1 + 11.28 - 1932t^* \quad (t^* \leq .05) \quad (\text{ft/sec})$$

Integrating once more gives the occupant displacement history

$$\omega_p = .4347 + (V_1 + 43.47)t^* + 149t^{*^2} -$$

$$16100t^{*^3} \quad (.03 \leq t^* \leq .05) \quad (\text{ft})$$

$$\omega_p = -1.5778 + (V_1 + 7.78)t^* - 96t^{*^2} \quad (t^* \leq .05 \text{ sec}) \quad (\text{ft})$$

V_1 is the velocity at impact.

The time t^* is most easily obtained by plotting the compartment velocity (obtained from test accelerometer data) and superimposing this curve on that obtained from D_p above. The time at which the curves cross gives t^* . The corresponding compartment displacement is determined from the test acceleration data. The occupant displacement at time t^* is determined from the D_p translation above.

The Available Interior Distance (AID) is determined for both pre-test and post-test compartment geometries under the following assumptions:

1. Knee restraint is located 6 inches forward of occupant's knee (horizontal rearward if there is sufficient room in the car). The occupant's knee joint is located by drawing a line tangent to the knee surface and parallel to the joint to the joint line. The California knee belt was a suitable homogeneous knee joint. It is part of the assumed passive restraint system. For the purpose of the AID calculation, the knee restraint is assumed to be 10 inches thick and capable of causing a force (both reaction and impact) in any direction during the collision.
2. The knee will contact the seatback into the restraint, or will travel to a point contact it from the deformed firewall, whichever joint is reached by the knee first. The transition is reformed under no reaction until the bottom of the foot reaches contact with the sloping part of the firewall (or as close to it as possible). Rotation therefore takes place about the occupant's ankle bone pivot point.
3. Having forced the occupant's knees by the preceding sequence of steps, the occupant is rotated about the ankle joint until either:
 - a. The head hits the header or windshield.
 - b. The chest hits the dash (steering column is ignored).
4. The AID is then the horizontal displacement of the chest center of gravity relative to the position when either of the above occurs. The chest C.G. is located 14 inch *down* the occupant point and 4 inches forward of the back of the torso.

2.0 DSI-CALSPAN RSD COMPARISON

An evaluation was made of the similarities and differences between the Dynamic Science and Calspan (Reference 1) results of fixed-barrier frontal crash tests on presumably identical 1975 Honda CVCC's.

Basic to the calculation of the RSD are the occupant and passenger compartment velocity and displacement time histories. These are derived from the respective acceleration profiles.

Figures D-2 and D-3 show the left and right compartment acceleration, velocity, and displacement histories for the DSI and for the Calspan tests. Superimposed on the velocity and displacement curves are the occupant velocity and displacement curves, for the DSI test conditions (initial velocity, 40.83 mph). [The Calspan occupant response curves would differ very little from these, since both are calculated on the basis of the standardized passive restraint deceleration pulse. The Calspan initial velocity was 40.25 mph.]

It is apparent from the acceleration curves (Figure D-2 and D-3) that there is a lag in the DST acceleration-time history. This is largely due to the difference in test configuration. The DSI fixed barrier includes a 6-inch-thick layer of aluminum honeycomb on the front face. In the DST tests, initial impact is defined as the instant of vehicle-honeycomb contact, since the test instrumentation detects this contact.

The occupant velocity and displacement curves shown in Figures D-2 and D-3 were calculated on the basis of this initial time instant. However, the occupant velocity and displacement equations are obtained by integrating the restraint deceleration pulse, assuming the initial restraint deployment-trigging signal and bag deployment requires 30 milliseconds. This signal would occur

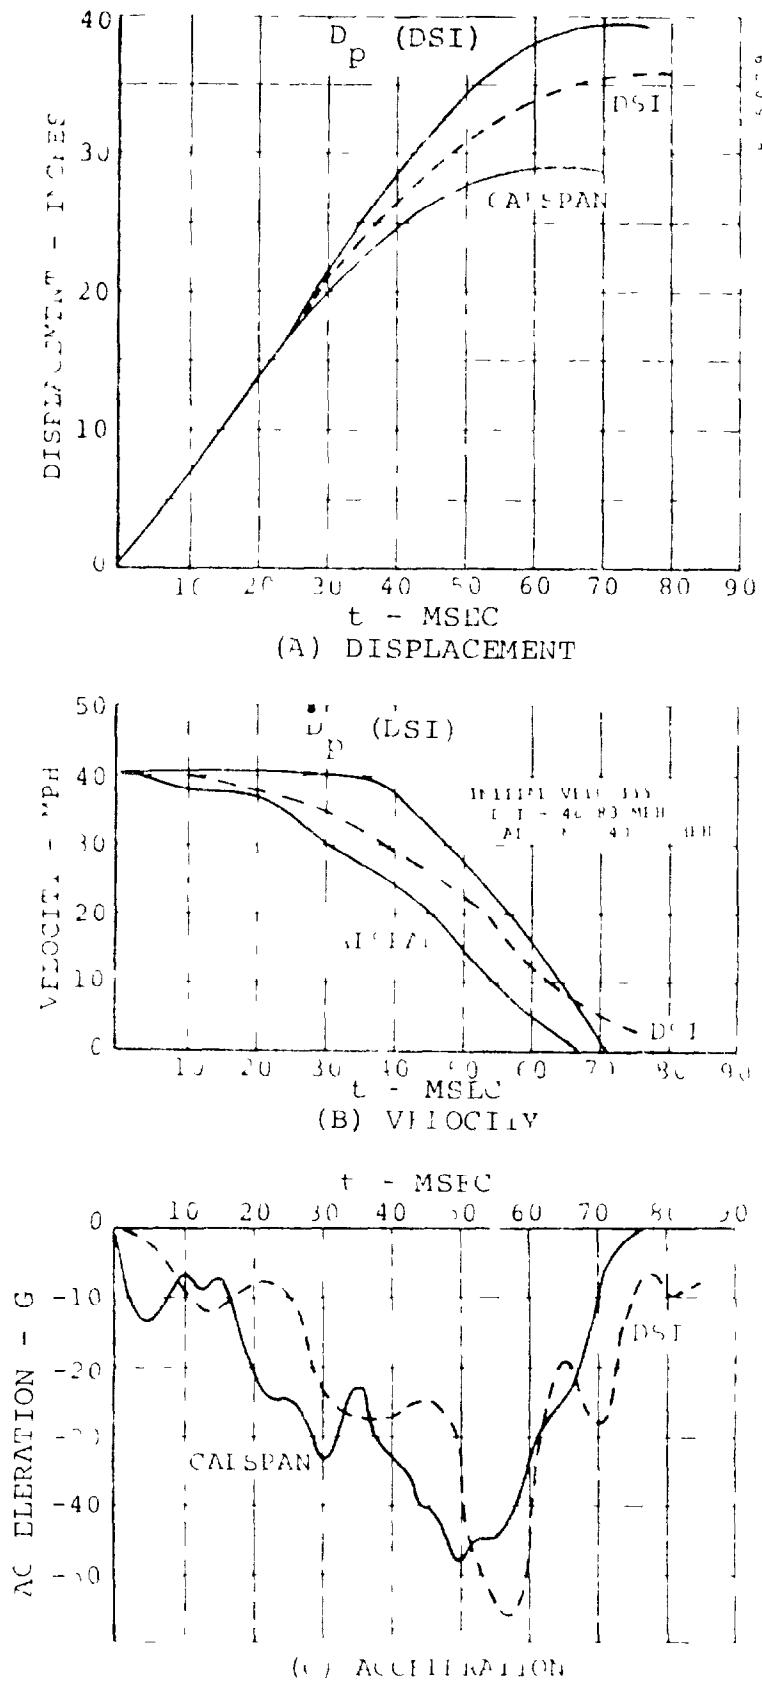

Figure D-2. 1975 Honda Civic - Fixed Barrier Test Left Compartment.

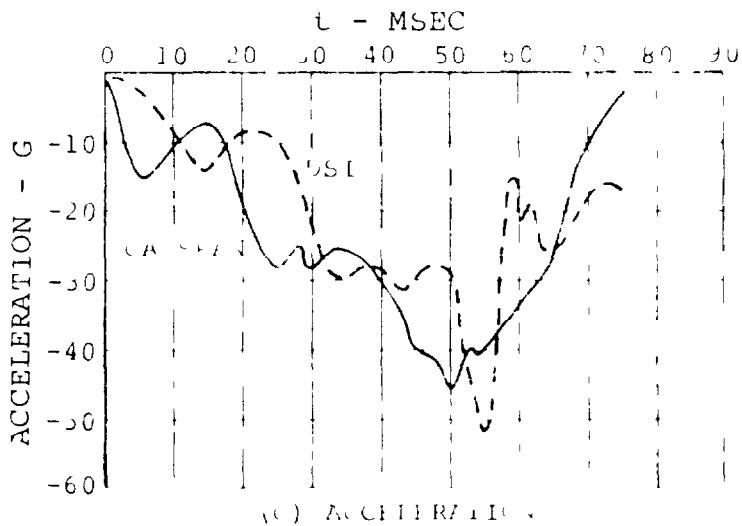

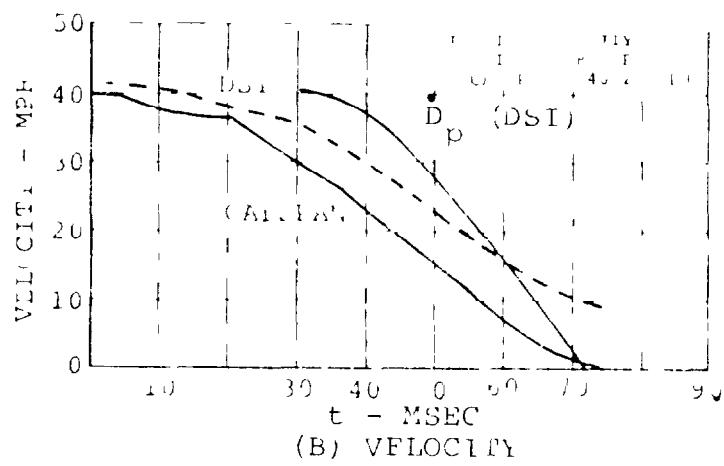

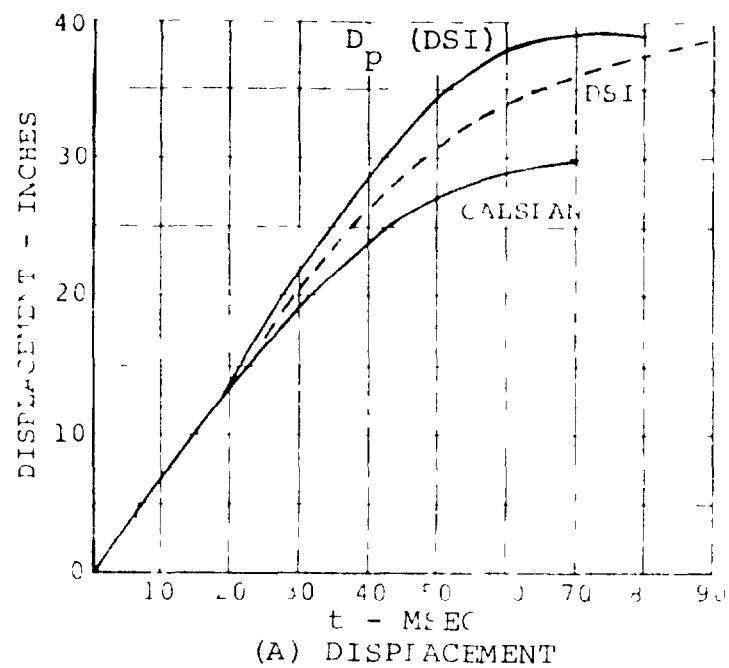

Figure D-3. 1975 Honda CVCC - Fixed Barrier Test
Right Compartment.

in the DSI test some time later and thus air bag deployment would be correspondingly delayed.

For purposes of comparison, the RSD's were recalculated assuming a 7-millisecond delay in the DSI restraint deployment signal. This corresponds to a constant velocity traversal of about 5 inches of honeycomb, at 40 mph. This delay produced changes in t^* , the time at which occupant velocity equals compartment velocity, and a corresponding change in the quantity $(D_p - D_c)$ which appears in the RSD equation. The AID's are not affected, being dependent only upon compartment geometry. Table D-1 summarizes these results, along with the corresponding Calspan values.

TABLE D-1. COMPARISON OF PSD'S DSI VERSUS CALSPAN -
1973 I-15 CYCLE-TO-FIXED BAR TEST

	Driver		Passenger	
	Pre	Post	Pre	Post
DSI (D_p curves not shifted)	6.2	15.5	6.2	9.6
DSI (D_p curves shifted 7 msec)	1.5	10.8	3.0	6.4
Calspan	1.0	3.9	1.8	4.5

All values are in inches.

It is apparent that taking the triggering signal delay into account produces better correlation between the Calspan and DSI tests. It should be pointed out that the use of a 7-millisecond delay is somewhat arbitrary since the actual restraint deployment signal is generated on the basis of compartment deceleration. Comparison of the acceleration curves of Figure D-3 and D-4 suggests that a 7-millisecond delay is reasonable. However, the comparative results are a good indication of the care that must be taken to ensure equivalent test evaluation procedures.
